<u>Lab Sheet 4 for CS F342 Computer Architecture</u> Semester 1 – 2020-2021

Goals for the Lab: To understand and use (1) the branch instructions and jump instructions, and (2) logical and shift operations.

MIPS does not have if statements, nor does it have for or while statements. To create conditional processing and loops it is necessary to build the control structure with branch statements. Normally, the execution of a statement is followed by the execution of the next statement in the code. A branch instruction causes execution to jump to a different statement. Some branches are conditional -- they only branch if a specified condition is met. Others are unconditional -- they always cause a branch to occur.

I) Branch Instructions: branch if a specified condition is met. All branch instructions use the I-format.

Name	Format		Meaning	Example	
Branch If Equal	beq	Rs,Rt,label	if Rs == Rt branch to label	beq	\$t1,\$t2,next
Branch If Not Equal	bne	Rs,Rt,label	if Rs != Rt branch to label	bne	\$t1,\$t2,else
Branch If Greater Than	bgt	Rs,Rt,label	if Rs > Rt branch to label	bgt	\$t1,\$t2,top
Branch If Less Than	blt	Rs,Rt,label	if Rs < Rt branch to label	blt	\$t1,\$t2,two
Branch If Greater Than or Equal	bge	Rs,Rt,label	if Rs >= Rt branch to label	bge	\$t1,\$t2,done
Branch If Less Than or Equal	ble	Rs,Rt,label	if Rs <= Rt branch to label	ble	\$t1,\$t2,three
Branch If Equal To Zero	beqz	Rs,label	if Rs == 0 branch to label	beqz	\$t1,after
Branch If Not Equal To Zero	bnez	Rs,label	if Rs != 0 branch to label	bnez	\$t1, second
Branch If Greater Than Zero	bgtz	Rs,label	if Rs > 0 branch to label	bgtz	\$t1,high
Branch If Less Than Zero	bltz	Rs,label	if Rs < 0 branch to label	bltz	\$t1,low
Branch If Greater Than or Equal To Zero	bgez	Rs,label	if Rs >= 0 branch to label	bgez	\$t1,somehi
Branch If Less Than or Equal To Zero	blez	Rs,label	if Rs <= 0 branch to label	blez	\$t1,somelo
Branch	b	label	branch to label	b	loop

The if-else construct:

Let's assume that the values of variables *var1* and *var2* are in registers **\$t0** and **\$t1**. Then, this piece of C code would be translated as:

Instructions like, *SLT* -- *Set on less than (signed), SLTI* - *Set on less than immediate (signed), and SLTU* -- *Set on less than (unsigned)* uses R-format.

Instruction	Example	Meaning	Comments
set on less than	slt \$1,\$2,\$3	if(\$2<\$3)\$1=1; else \$1=0	Test if less than. If true, set \$1 to 1. Otherwise, set \$1 to 0.
set on less than immediate	slti \$1,\$2,100	if(\$2<100)\$1=1; else \$1=0	Test if less than. If true, set \$1 to 1. Otherwise, set \$1 to 0.

The sltu instruction is used with unsigned integers: sltu d,s,t # if (\$s < \$t) d = 1 else d=0.

Exercise 1: Write MIPS code to find the minimum and maximum of two integer numbers.

```
# Find max $t0 and $t1
bge $t0,$t1,ifblock # Check if $t0>=$t1, $t0 is maximum, then go to ifblock (label)
move $t2,$t1
                 # Else, $t1 is maximum
blt $t0,$t1,exit
ifblock:
move $t2,$t0
exit:
# Display the Max
la $a0,output_msg1
li $v0,4
syscall
move $a0,$t2
li $v0,1
svscall
# Find min $t0 and $t1
ble $t0,$t1,ifblock1 # Check if $t0<=$t1, $t0 is min, then go to ifblock (label)
move $t2,$t1
                 # Else, $t1 is min
bgt $t0,$t1,exit1
ifblock1:
move $t2,$t0
exit1:
# Display the Min
la $a0,output_msg2
li $v0,4
syscall
move $a0,$t2
li $v0,1
syscall
```

Exercise 2: Write MIPS code to find the input integer is even or odd.

```
li $t1,2
div $t0,$t1
mfhi $t0

# Find max $t0 and $t1
beqz $t0,ifblock # if($t0%2==0) goto ifblock and print even

la $a0,output_msg1 # Else, print odd
li $v0,4
syscall
bnez $t0,exit

ifblock:
la $a0,output_msg # Else, print even
li $v0,4
syscall
exit:
```

II) Jump Instructions: an instruction which unconditionally branches to a labeled instruction. We use jump instructions.

Instruction	Meaning
j label	Unconditionally jump to the instruction at the label.
jal label	Jump and Link; Typically used in function calls.
jr Rsrc	Unconditionally jump to the instruction whose address is in register Rsrc.

The C while and MIPS

The C *while* expression closely resembles the *if* expression. It has a predicate and something that happens continuously as long as the expression returns true.

The C for and MIPS

The *for* expression is like the while expression except it has two addition components to it. Not only does it have the *consequent* body which is evaluated continuously as long as the predicate returns a true value, it has *initialization* and *next* statements built into it. It would look as follows:

Notice how it's form doesn't really change that much from the while loop. It's really just a construct in C to make code more compressed and readable. The form in MIPS looks like:

Exercise 3: Write MIPS code to find the sum of first n natural numbers.

```
.data
input_msg: .asciiz "Enter a number: "
output_msg: .asciiz "The sum "

.text
main:
```

```
# Read integer number n
la $a0,input_msg
li $v0,4
syscall
li $v0.5
syscall
move $t3,$v0 # $t3 contains n
li $t0,0 # intialize sum =0.
li $t1,0 # intialize count =0
loop:
  bgt $t1,$t3,exit # while count>n, come out of loop
  add $t0,$t0,$t1 # sum=sum+count
  addi $t1,$t1,1 # increment count
  j loop
exit:
# Display the sum
la $a0,output_msg
li $v0,4
syscall
move $a0,$t0
li $v0,1
syscall
# Exit the program
li $v0,10
syscall
```

III) Floating point branch instructions:

Conditional jumps are performed in two stages:

- 1. Comparison of FP values sets a code in a special register
- 2. Branch instructions jump depending on the value of the code.

```
Instruction
                 Operation
                 set floating point coprocessor flag true if equal double
c.eq.d $f0,$f12
                 set floating point coprocessor flag true if equal float
c.eq.s $f0,$f12
                 set floating point coprocessor flag true if greater or equal double
c.ge.d $f0,$f12
c.ge.s $f0,$f12
                 set floating point coprocessor flag true if greater or equal float
                 set floating point coprocessor flag true if greater than double
c.gt.d $f0,$f12
                 set floating point coprocessor flag true if greater than float
c.gt.s $f0,$f12
c.le.d $f0,$f12
                 set floating point coprocessor flag true if less or equal double
c.le.s $f0,$f12
                 set floating point coprocessor flag true if less or equal float
                 set floating point coprocessor flag true if less than double
c.lt.d $f0,$f12
c.lt.s $f0,$f12
                 set floating point coprocessor flag true if less than float
                set floating point coprocessor flag true if not equal double
c.ne.d $f0.$f12
c.ne.s $f0,$f12
                 set floating point coprocessor flag true if not equal float
```

The floating point compare instructions set or clear the floating point coprocessor flag. The bc1t (flag true) and bc1f (flag false) instructions can then be used for branching conditioned on the comparison result. [Note: Some of the above instructions are not available in QtSpim.]

Instruction	Example	Meaning
bc1t	bc1t label	Branch to label if condition flag 0 is true
bc1t	bc1t 1, label	Branch to label if condition flag 1 is true
bc1f	bc1f label	Branch to label if condition flag 0 is false
bc1f	bc1f 4, label	Branch to label if condition flag 4 is false

Exercise 4: Write MIPS code to find the minimum and maximum of two floating point numbers.

```
.data
input_msg1: .asciiz "Enter first number"
input_msg2: .asciiz "Enter second number"
output_msg1: .asciiz "The Maximum is :"
output_msg2: .asciiz "The Minimum is :"
.text
main:
# Read first number
la $a0,input_msg1
li $v0,4
syscall
li $v0,6
syscall
mov.s $f1,$f0
# Read second number
la $a0,input_msg2
li $v0,4
syscall
li $v0,6
syscall
mov.s $f2,$f0
# Find max $f1 and $f2
c.lt.s $f1,$f2 # Check if $f1>=$f2, $f1 is maximum, then go to ifblock (label)
bc1f ifblock
mov.s $f4,$f2
                    # Else, $f2 is maximum
c.lt.s $f1,$f2
bc1t exit
ifblock:
mov.s $f4,$f1
exit:
# Display the Max
la $a0,output_msg1
li $v0,4
syscall
mov.s $f12,$f4
li $v0,2
syscall
# Find min $f1 and $f2
c.lt.s $f1,$f2
              # Check if $f1<=$f2, $f1 is min, then go to ifblock (label)
bc1t ifblock1
c.lt.s $f1,$f2
bc1f else1
```

```
ifblock1:
mov.s $f4,$f1

else1:
mov.s $f4,$f2

# Display the Min
la $a0,output_msg2
li $v0,4
syscall
mov.s $f12,$f4
li $v0,2
syscall

# Exit the program
li $v0,10
syscall
```

IV) Logical and Shift operations : MIPS has two types of bitwise instructions: those that operate on registers, and those that operate on a register and an immediate operand. The register instructions are:

- (1) and Rd, Rs, Rt
- (2) or Rd, Rs, Rt
- (3) nor Rd, Rs, Rt
- (4) xor Rd, Rs, Rt

The immediate insructions are:

- (1) andi Rt, Rs, immed
- (2) ori Rt, Rs, immed
- (3) xori Rt, Rs, immed

Example 1: By ANDing a value with a deliberately designed constant, called a bit mask we can clear specific bits. Any bits that are 0 in the mask will be cleared in the result, and bits that are 1 in the mask with be preserved in the result.

```
value 10010100
mask 00001111
------
```

Shift instructions:

- Left shift: Moves bits from a lower position to a higher position.
- Right shift: Moves bits from a higher position to a lower position.

sll \$t0,\$t1,5 shift left logical srl \$t0,\$t1,5 shift right logical sra \$t0,\$t1,5 shift right arithmetic sllv \$t0,\$t1,\$t2 shift left logical value (register) srlv \$t0,\$t1,\$t2 shift right logical value (register) srav \$t0,\$t1,\$t2 shift right arithmetic value (register)

Exercise 5: Give MIPS instruction to perform the following:

(a) Returns in \$v0, 0 and 1 depending on the most significant bit of input stored in \$a

[Answer: srl \$v0, \$a0, 31]

(b) Flip (Replace 0's and 1's)

[Answer : xor \$v0, \$a0, -1]

(c) To perform NOT operation, using logical operations.
